Chance or Tolerance Probability of an Confidence Interval

Chao Cheng

September 23, 2022

1 Introduction

When a Confidence Interval(CI) is constructed, usually its upper and lower limits (for a two-sided interval) is random variables. And the probability that this interval will cover (or more precisely, the lower limit will be smaller than and at the same time the upper limit will be greater than) the value in interest, e.g population mean, is the confidence level, usually denoted by $1-\alpha$.

Since both upper and lower limits are random variables, the length (or some times, half of the interval length) is also a random variable. And in some projects, we want to make some statement about the property of this length. Usually we want to quantify the probability that this (half) width of CI is smaller than a specified value. In different literature, this is called the **chance** of CI lies in the width, or the **tolerance probability** of the CI at given width.

In this notes, we will be using CI for normal mean as an example.

2 Construct $(1-\alpha)$ CI

For a random sample

$$x_1, \cdots, x_n \overset{i.i.d}{\sim} N\left(\mu, \sigma^2\right),$$

where μ and σ^2 are both unkonwn, we konw that

$$\frac{\bar{x}-\mu}{\sqrt{S^2/n}} \sim t_{n-1},$$

where $S^2 = \frac{1}{n-1}\sum_{i=1}^{2}\left(x_i-\bar{x}\right)^2$ is sample variance. Then the $1-\alpha$ CI for μ is just

$$\left[\bar{x}-t_{1-\alpha/2,n-1}\cdot\sqrt{\frac{S^2}{n}}, \quad \bar{x}+t_{1-\alpha/2,n-1}\cdot\sqrt{\frac{S^2}{n}}\right].$$

And the **half** length d of this interval is just

$$d \triangleq t_{1-\alpha/2,n-1}\cdot\sqrt{\frac{S^2}{n}}.$$

3 Computation of the chance at given d_0

Note that for a normal sample,

$$\frac{(n-1)\,S^2}{\sigma^2} \sim \chi^2_{n-1}.$$

Therefore

$$\begin{aligned}
P\left(d \le d_0\right) =& P\left(t_{1-\alpha/2,n-1} \cdot \sqrt{\frac{S^2}{n}} \le d_0\right) \\
=& P\left(\frac{(n-1)\,S^2}{\sigma^2} \le \frac{n\,(n-1)\,d_0^2}{t^2_{1-\alpha/2,n-1}\sigma^2}\right) \\
=& P\left(X^2_{n-1} \le \frac{n\,(n-1)\,d_0^2}{t^2_{1-\alpha/2,n-1}\sigma^2}\right).
\end{aligned}$$

Hence the chance of this CI falls in the half width limit of d_0 is the probability of a χ^2 random variable X^2_{n-1} with $n-1$ degree of freedom being smaller than

$$\frac{n\,(n-1)\,d_0^2}{t^2_{1-\alpha/2,n-1}\sigma^2}.$$

4 Additional notes and resources

- In Pharmocokinect(PK) analysis, the samples $z_1, \cdots, z_n$ for PK parameters are often assumed to follow log-normal distribution, which means $x_i = \log(z_i)$ follows normal distribution and the analysis is often down on this log-scale, then transformed back to original scale. Note that for $\mathrm{E}X = \mu$ and $\mathrm{Var}X = \sigma^2$, we have

  $$\mathrm{E}Z = e^{\mu+\frac{\sigma^2}{2}}, \quad \mathrm{Var}Z = e^{2\mu+\sigma^2}\left(e^{\sigma^2}-1\right).$$

  And the Coefficient of Variation(CV) at original scale satisfies

  $$CV = \frac{\sqrt{\mathrm{Var}Z}}{\mathrm{E}Z} = \sqrt{e^{\sigma^2}-1}.$$

  Note that in PK, CV is often offerd instead of σ^2.
